Galvanizing Process

BAKRIYA INDUSTRIES CO. LTD. – HOT-DIP GALVANIZING (BGC)

BGC is professionally engaged in the production of all kinds of Hot-Dip Galvanizing process.

HOT-DIP GALVANIZING PROCESS:

GALVANIZING:

In the true galvanizing step of the process, the material is completely immersed in a bath of molten zinc. The bath contains at least 98% pure zinc and is heated to approximately 840 F (449 C). Zinc chemistry is specified by ASTM B 6. While immersed in the kettle, the zinc reacts with the iron in the steel to form a series of zinc/iron intermetallic alloy layers. Once the fabricated items coating growth is complete, they are withdrawn slowly from the galvanizing bath, and the excess zinc is removed by draining, vibrating, and/or centrifuging. The metallurgical reaction will continue after the articles are withdrawn from the bath, as long as the article remains near bath temperature. Articles are cooled either by immersion in a passivation solution or water or by being left in open air. Hot-dip galvanizing is a factory-controlled process performed under any climate conditions. Most brush-and spray-applied coatings depend upon proper climate conditions for correct application. Dependence on atmospheric conditions often translates into costly construction delays. The galvanizer's ability to work in any climate conditions provides a higher degree of assurance of on-time delivery; furthermore, no climate restrictions means galvanizing can be completed quickly and with short lead times.

The Hot-Dip Galvanizing process consists of three basic steps: Surface Preparation, Galvanizing, and Inspection.

Surface Preparation

Surface preparation is the most important step in the application of any coating. In most instances, incorrect or inadequate surface preparation is the cause of a coating failure before the end of its expected service lifetime. The surface preparation step in the galvanizing process has its own built-in means of quality control because zinc will not metallurgically react with an unclean steel surface. Any failures or inadequacies in surface preparation will immediately be apparent when the steel is withdrawn from the molten zinc, because the unclean areas will remain uncoated and immediate corrective action must be taken.

Surface preparation for galvanizing consists of three steps: **Degreasing, Acid Pickling, and Fluxing.**

DEGREASING - A hot alkali solution, mild acidic bath, or biological cleaning bath removes organic contaminants such as dirt, paint markings, grease, and oil from the steel surface. Degreasing baths cannot remove epoxies, vinyl, asphalt, or welding slag; thus, these materials must be removed by grit-blasting, sand-blasting, or other mechanical means before the steel is sent to the galvanizer.

PICKLING - A dilute solution of hot sulfuric acid or ambient temperature hydrochloric acid removes mill scale and iron oxides (rust) from the steel surface. As an alternative to or in conjunction with pickling, this step can also be accomplished using abrasive cleaning, air blasting sand, metallic shot, or grit onto the steel.

FLUXING - The final surface preparation step in the galvanizing process serves two purposes. It removes any remaining oxides and deposits a protective layer onto the steel to prevent any further oxides from forming on the surface prior to galvanizing. Flux is applied in two different ways; wet or dry. In the dry galvanizing process, the steel or iron is dipped or pre-fluxed in an aqueous solution of zinc ammonium chloride. The material is then dried prior to immersion in molten zinc. In the wet galvanizing process, a layer of liquid zinc ammonium chloride is floated on top of the molten zinc. The iron or steel being galvanized passes through the flux on its way into the molten zinc.
